MODELING AND FORECASTING AGE-AT-DEATH DISTRIBUTIONS

Ugofilippo Basellini & Carlo Giovanni Camarda

Taipei, 21st September 2017

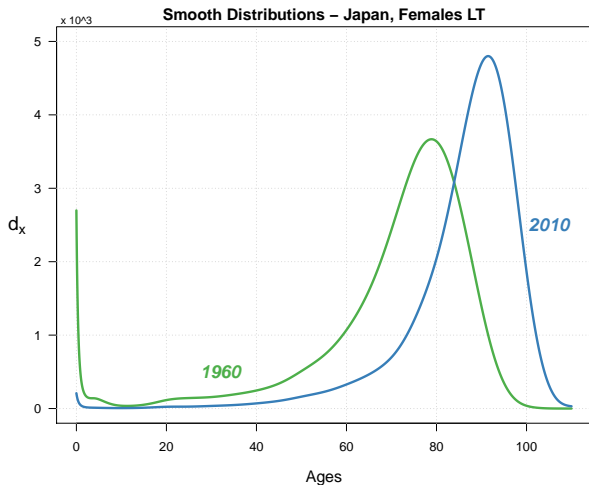

Motivation

- ▶ **Background:**
 - ▶ mortality modeling and forecasting are generally based on mortality rates
 - ▶ age-at-death distributions are very informative, yet neglected for modeling and forecasting

Motivation

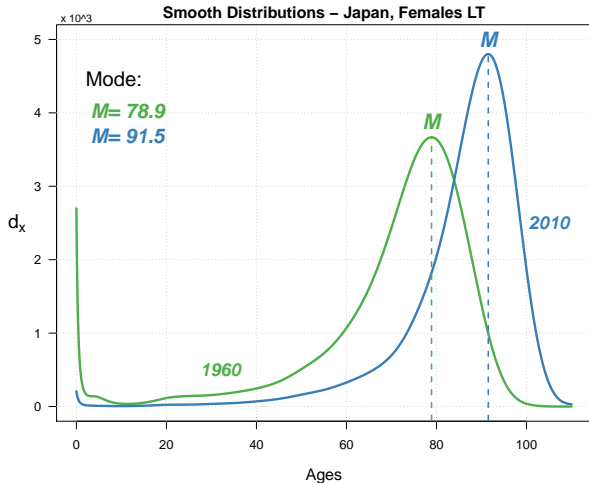

- ▶ **Background:**
 - ▶ mortality modeling and forecasting are generally based on mortality rates
 - ▶ age-at-death distributions are very informative, yet neglected for modeling and forecasting
- ▶ **Research question:** model and forecast mortality by studying changes in age-at-death distributions

Age-at-death Distributions

Summary measures:

Age-at-death Distributions

Summary measures:

- ▶ Longevity = Modal age at death

Age-at-death Distributions

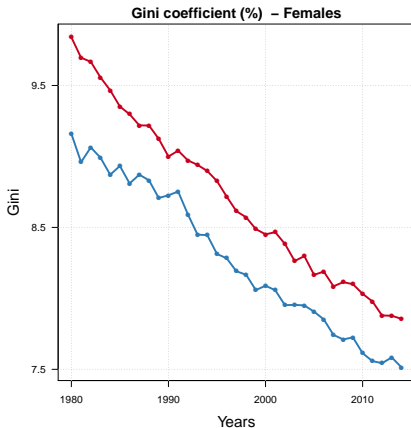

Summary measures:

- ▶ Longevity = Modal age at death
- ▶ Lifespan Inequality = (Relative) variability of death distribution

Longevity & Lifespan Inequality

Joint trends studied extensively, but hard to disentangle age-specific contributions

The STAD Model

Notation:

- ▶ x : age
- ▶ $f(x)$: standard distribution
- ▶ $g(x)$: observed distribution
- ▶ $t(x)$: transformation function

The STAD Model

Notation:

- ▶ x : age
- ▶ $f(x)$: standard distribution
- ▶ $g(x)$: observed distribution
- ▶ $t(x)$: transformation function

Aim: Look for a $t(x)$ such that:

- ▶ $g(x)$ conforms to $f(x)$ on the warped axis, i.e. $g(x) = f(t(x))$

The STAD Model

Notation:

- ▶ x : age
- ▶ $f(x)$: standard distribution
- ▶ $g(x)$: observed distribution
- ▶ $t(x)$: transformation function

Aim: Look for a $t(x)$ such that:

- ▶ $g(x)$ conforms to $f(x)$ on the warped axis, i.e. $g(x) = f(t(x))$
- ▶ $t(\cdot)$ is a **segmented function** of the difference in modal ages and the change in the variability before and after M :

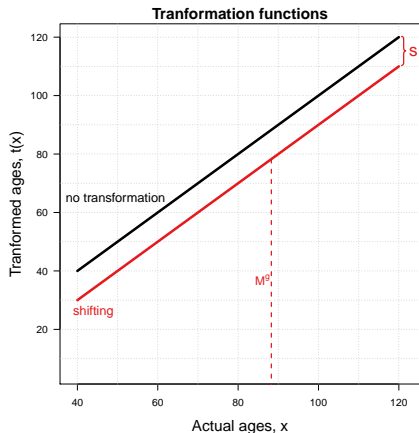

$$t(x; s, b_L, b_U) = \begin{cases} M^f + b_L (x - s - M^f) & \text{if } x \leq M^g \\ M^f + b_U (x - s - M^f) & \text{if } x > M^g \end{cases}$$

The STAD Model

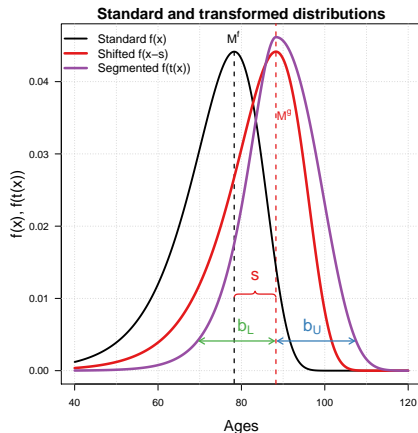

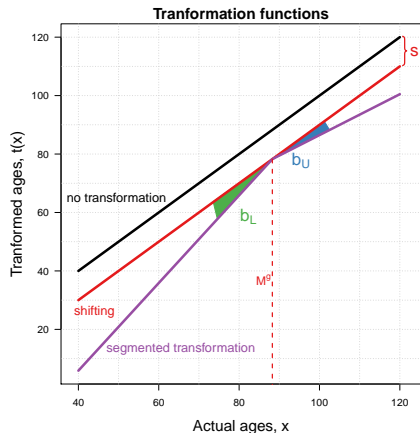

The STAD Model

$s = M^g - M^f$ is the difference between the M of $g(x)$ and $f(x)$
(*shifting* dynamic of mortality)

The STAD Model

b_L and b_U measure the change in lifespan variability of $f(x - s)$ before and after M^g (compression dynamic of mortality)

The Standard Distribution

- ▶ **Relational models:** theoretical framework, transformed $f(x)$ captures mortality developments *over time*

The Standard Distribution

- ▶ **Relational models:** theoretical framework, transformed $f(x)$ captures mortality developments *over time*

⇒ choice of $f(x)$ is important and should be made with care

The Standard Distribution

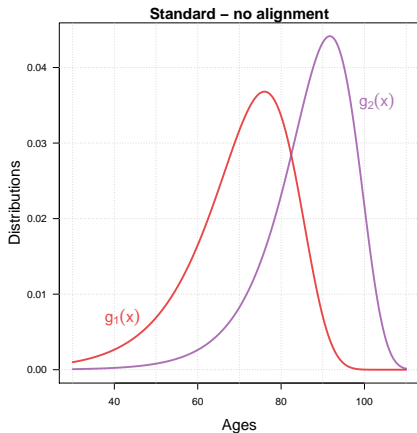

- ▶ **Relational models:** theoretical framework, transformed $f(x)$ captures mortality developments *over time*

⇒ choice of $f(x)$ is important and should be made with care
- ▶ **Landmark registration:** alignment of observed densities to the mode of the first distribution

The Standard Distribution

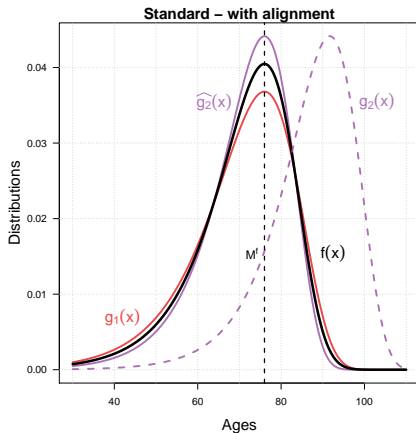

The Standard Distribution

The Standard Distribution

The Standard Distribution

Application to observed data

► **Smoothing:**

- apply continuous model to discrete data
- avoid rigid parametric mortality structure

Application to observed data

- ▶ **Smoothing:**
 - ▶ apply continuous model to discrete data
 - ▶ avoid rigid parametric mortality structure
- ▶ **Estimation:** for each year, b_L and b_U estimated by maximum likelihood from the assumption:

$$D_x \sim \text{Poisson}(E_x \mu_x)$$

Application to observed data

► **Smoothing:**

- apply continuous model to discrete data
- avoid rigid parametric mortality structure

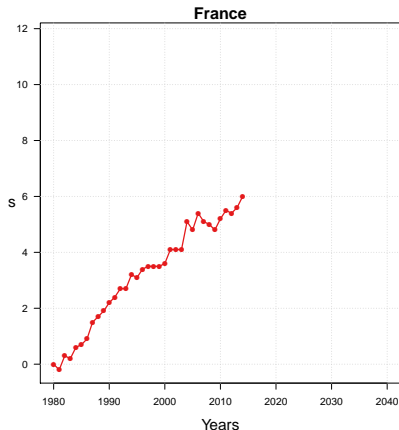

- **Estimation:** for each year, b_L and b_U estimated by maximum likelihood from the assumption:

$$D_x \sim \text{Poisson}(E_x \mu_x)$$

- **Data:** observed death counts and exposure times for females aged 30+ during 1980-2014 in Sweden and France (retrieved from the Human Mortality Database)

Estimation

Shifting parameter s :

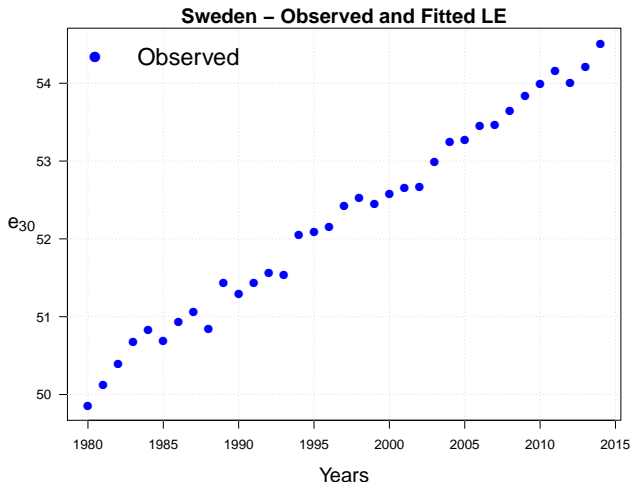

Estimation

Compression/expansion parameters b_L and b_U :

Observed vs Fitted Data

Good performance in terms of goodness-of-fit:

Summary

- ▶ One of the very first attempts of modeling and forecasting mortality from age-at-death distributions

Summary

- ▶ One of the very first attempts of modeling and forecasting mortality from age-at-death distributions
- ▶ Segmented linear transformation of the ages allows to capture mortality development very parsimoniously

Summary

- ▶ One of the very first attempts of modeling and forecasting mortality from age-at-death distributions
- ▶ Segmented linear transformation of the ages allows to capture mortality development very parsimoniously
- ▶ Good performance of the model in terms of goodness-of-fit

Summary

- ▶ One of the very first attempts of modeling and forecasting mortality from age-at-death distributions
- ▶ Segmented linear transformation of the ages allows to capture mortality development very parsimoniously
- ▶ Good performance of the model in terms of goodness-of-fit
- ▶ Forecast remaining life expectancy reflects well the past linear increase and it is more optimistic than the Lee-Carter model

Future work

- ▶ Extension to the entire age range

Future work

- ▶ Extension to the entire age range
- ▶ Application to longevity risk products & pricing comparison against other models

Future work

- ▶ Extension to the entire age range
- ▶ Application to longevity risk products & pricing comparison against other models
- ▶ Application to cause-specific mortality

Thanks for your attention.

Comments and/or questions?
